NAME OF THE MEDICINE

Fosinopril + Hydrochlorothiazide 10 + 12.5 mg

Each tablet contains:
Fosinopril sodium 10 mg
Hydrochlorothiazide Ph. Eur. 12.5 mg

Fosinopril + Hydrochlorothiazide 20 + 12.5 mg

Each tablet contains:
Fosinopril sodium 20 mg
Hydrochlorothiazide Ph. Eur. 12.5 mg

DESCRIPTION

APO-Fosinopril HCTZ 20/12.5 mg tablets contain Fosinopril sodium and hydrochlorothiazide.

Fosinopril sodium

Fosinopril sodium is the ester prodrug of a long-acting angiotensin converting enzyme (ACE) inhibitor, fosinopril diacid. It is a sub-class of ACE inhibitors containing a phosphinate group which makes it different from other marketed ACE inhibitors. Fosinopril sodium is designated chemically as: L-proline, 4-cyclohexyl-1-[[2-methyl-1- (1-oxoproxy) propoxy] (4-phenylbutyl) phosphiny]acyethyl]-, sodium salt, trans-. The empiric formula of fosinopril sodium is C_{30}H_{45}NaO_{7}P. The molecular weight of fosinopril sodium is: 585.65.

Fosinopril Sodium Structure

![Fosinopril Sodium Structure](image)

Hydrochlorothiazide Structure

![Hydrochlorothiazide Structure](image)
Hydrochlorothiazide

Hydrochlorothiazide is the 3,4-dihydro derivative of chlorothiazide, defined chemically as 6-chloro-3,4-dihydro-2H-1,2,4-benzothiadiazine-7-sulphonamide 1,1-dioxide. The empirical formula of hydrochlorothiazide is: $C_{7}H_{8}CIN_{3}O_{4}S_{2}$ and molecular Weight is: 297.72.

APO-Fosinopril HCTZ 10/12.5 mg and APO-Fosinopril HCTZ 20/12.5 mg tablets contain the following inactive ingredients: Anhydrous Lactose, Crospovidone, Povidone, Microcrystalline Cellulose, Colloidal Anhydrous Silica, Purified Talc.

PHARMACOLOGY

Pharmacodynamics

Fosinopril sodium

In humans and animals, fosinopril sodium following absorption is hydrolysed to the pharmacologically active fosinopril diacid, a specific competitive inhibitor of angiotensin converting enzyme (ACE).

ACE, a peptidyldepeptidase, catalyzes the conversion of the decapeptide angiotensin I to the octapeptide angiotensin II. Angiotensin II is a potent vasoconstrictor and it also stimulates aldosterone secretion by the adrenal cortex, thereby contributing to sodium and fluid retention. The effects of fosinopril in hypertension appear to result primarily from inhibition of angiotensin II formation and decreased aldosterone secretion. Inhibition of ACE activity leads to decreased levels of angiotensin II, thereby resulting in diminished vasoconstriction, aldosterone secretion, peripheral vascular resistance, and sodium and fluid retention. Decreased levels of angiotensin II and the accompanying lack of negative feedback on renal secretion results in increases in plasma renin activity. Decreased level of aldosterone results in small increase of serum potassium.

Inhibition of ACE also interferes with the degradation of bradykinin a potent vasodepressor peptide, which may contribute to the therapeutic effect.

While the mechanism through which fosinopril lowers blood pressure is believed to be primarily suppression of the renin-angiotensin-aldosterone system, fosinopril has an antihypertensive effect even in patients with low-renin hypertension. Although fosinopril was antihypertensive in all races studied, black hypertensive patients (usually a low-renin hypertensive population) had a smaller average response to ACE inhibitor monotherapy than non-black patients.

Hydrochlorothiazide

The mechanism of antihypertensive effect of hydrochlorothiazide is unknown. Thiazide diuretics affect the renal tubular mechanisms of electrolyte reabsorption, increasing excretion of sodium and chloride in approximately equivalent amounts. Naturenix causes a secondary loss of potassium and bicarbonate. Hydrochlorothiazide increases plasma renin activity, increases aldosterone secretion and decreases potassium. Concurrent administration of fosinopril attenuates the potassium loss associated with hydrochlorothiazide.

With hydrochlorothiazide, the onset of diuresis occurs in 2 hours, and peak effect at about 4 hours, and the action persists for approximately 6-12 hours.

Pharmacokinetics

In single dose studies in healthy volunteers concomitant administration of fosinopril and hydrochlorothiazide had little or no effect on the pharmacokinetics of either drug. Kinetic parameters for each constituent derived following either monotherapy or combination therapy are:

Fosinopril sodium

Absorption

The extent of absorption for fosinopril is 30-40% and is essentially unaffected by food although the rate of absorption may be slowed.

The time to peak plasma concentrations of fosinopril diacid is approximately 3 hours and is independent of the dose of fosinopril administered. After single and multiple oral doses $C_{\text{max}}$ and AUC are directly proportional to the administered dose of fosinopril.
**Distribution**

Fosinopril diacid is highly protein bound (≥ 95%) but has negligible binding to cellular components of blood. It has a relatively small volume of distribution. Studies in animals indicate that fosinopril and fosinopril diacid do not cross the blood-brain barrier but fosinopril diacid does cross the placenta of pregnant animals.

**Metabolism**

In healthy subjects and renally impaired patients, hydrolysis of fosinopril to the active fosinopril diacid is rapid and complete. This transformation probably occurs in the gastrointestinal mucosa and liver. After an oral dose of radiolabeled fosinopril, 75% of radioactivity in plasma was present as active fosinopril diacid, 20-30% as glucuronide conjugate and 1-5% as a \( p \)-hydroxy metabolite. The \( p \)-hydroxy metabolite is as potent an inhibitor of ACE as fosinopril diacid; the glucuronide conjugate is devoid of ACE inhibitory activity. The conversion of fosinopril to fosinopril diacid may be slowed in patients with hepatic dysfunction although the extent of this conversion is unchanged.

**Excretion**

After intravenous administration, fosinopril diacid is eliminated approximately equally by the liver and kidneys. In healthy subjects, mean body clearance of IV fosinopril diacid was 26-39 mL/min. In hypertensive patients, with normal renal and hepatic function who received repeated doses of fosinopril, the effective \( t_{1/2} \) for the accumulation of fosinopril diacid averaged 11.5 hours. Fosinopril is not well dialysed with the clearance of fosinopril diacid by haemodialysis and peritoneal dialysis averaging 2% and 7% of urea clearance respectively.

**Hydrochlorothiazide**

**Absorption**

The extent of absorption for hydrochlorothiazide is 50-80%. Peak plasma concentrations of hydrochlorothiazide are reached approximately 2 hours after oral administration.

**Distribution**

Its apparent volume of distribution is 0.83 - 1.141 L/kg and its plasma protein binding is 68%. Hydrochlorothiazide does not cross the blood-brain barrier but does cross the placenta freely producing foetal plasma levels similar to those found in the maternal circulation.

**Metabolism & Excretion**

Hydrochlorothiazide is not metabolised and is eliminated rapidly by the kidney. The mean plasma half life ranged from 4 hours in young subjects to 11 hours in the elderly.

**Pharmacokinetics in special populations**

**Renal impairment**

The pharmacokinetics of fosinopril diacid and hydrochlorothiazide were examined following administration of one Fosinopril + hydrochlorothiazide 20/12.5 tablet once daily for 5 days, in subjects with renal impairment (mean creatinine clearance 56 mL/min; range 27 -76) and a group with normal renal function. Renal impairment lead to increased serum concentrations of fosinopril diacid and hydrochlorothiazide with repeated administration. On day 5, the ratio of AUC geometric mean in the renal impaired group/ geometric mean in the normal group was 1.43 for fosinopril diacid and 2.24 for hydrochlorothiazide. Increased fosinopril diacid concentrations were reflected by greater ACE inhibition. It is not clear that steady state would have been reached for fosinopril diacid in the renally-impaired patients by day 5, so fosinopril diacid levels in such patients during chronic administration may be higher than in this study.

These findings are of no significance for patients who have been stabilized on coadministered fosinopril and hydrochlorothiazide before switching to Fosinopril + hydrochlorothiazide, as dose titration will have already taken place.

**Hepatic insufficiency (alcoholic or biliary cirrhosis)**

No information is available from studies involving concurrent administration of fosinopril and hydrochlorothiazide. In studies using fosinopril alone, the extent of hydrolysis of fosinopril is not appreciably reduced, although the rate of hydrolysis may be slowed. The apparent total body clearance of fosinopril diacid is approximately one-half that in patients with normal hepatic function.
Elderly
In elderly male subjects (66-75 years old) with clinically normal renal and hepatic function, the mean peak concentration and systemic exposure of fosinopril diacid were respectively 21% (single dose) & 44% (multiple dose) and 19% (single dose) & 23% (multiple dose) greater than those observed in the young subjects (21-30 years old). For hydrochlorothiazide, the mean peak serum/plasma concentration was increased by 27% (single dose) and 39% (multiple dose) for the elderly group compared to the young subjects. The area under the plasma concentration time curve (AUC) for hydrochlorothiazide was increased by 91% in the elderly group following multiple dosing.

Clinical Trials
Both agents reduce blood pressure by different but complementary mechanisms and are used in combination for the treatment of hypertension. Clinical studies have shown that blood pressure reduction achieved with the combination of fosinopril and hydrochlorothiazide was approximately additive. Peak blood pressure reductions were achieved 6-8 hours after dosing and the hypertensive effect persisted for 24 hours. Symptomatic postural hypotension was infrequent but can occur in patients who are salt and/or volume depleted. Once daily doses of fosinopril and hydrochlorothiazide lowered 24 hour trough, seated systolic/diastolic blood pressure by 10-17mm Hg/ 6-7 mm Hg (10 mg/12.5 mg dose) and 11- 13mm Hg/ 7- 8 mm Hg (20 mg/12.5 mg dose) when compared to placebo in the intention-to-treat population. These trough effects were 60-90% of the corresponding peak response. The effectiveness of the fosinopril/hydrochlorothiazide combination was not influenced by age, sex or race. Abrupt withdrawal of the combination did not result in rebound hypertension.

INDICATIONS
APO-Fosinopril HCTZ 10/12.5 mg and APO-Fosinopril HCTZ 20/12.5 mg Tablets are indicated for the treatment of mild to moderate hypertension. Treatment should not be initiated with these combinations.

CONTRAINDICATIONS
APO-Fosinopril HCTZ 10/12.5 mg and APO-Fosinopril HCTZ 20/12.5 mg tablets are contraindicated in patients with:

- Hypersensitivity to fosinopril sodium or hydrochlorothiazide, other ACE inhibitors or other sulphonamide derived drugs (e.g. thiazides) or any of the inactive components of the tablets.
- History of hereditary and/or idiopathic angioedema or angioedema associated with previous treatment with an angiotensin converting enzyme inhibitor.
- Pregnancy (see Use in Pregnancy)
- Anuria.

PRECAUTIONS
General
Anaphylactoid And Possibly Related Reactions

Head and neck angioedema
Severe life-threatening angioedema has been reported rarely with angiotensin converting enzyme (ACE) inhibitors. The overall incidence is approximately 0.1% to 0.2%. There seems to be no sex difference in the incidence of angioedema or in the predisposition to angioedema in patients with heart failure or hypertension. In the majority of reported cases, the symptoms occurred during the first week of therapy. However, the onset of angioedema may be delayed for weeks or months. Patients may have multiple episodes of angioedema with long symptom-free intervals. The aetiology is thought to be non-immunogenic and may be related to accentuated bradykinin activity. Angioedema may occur with or without urticaria but usually the angioedema involves non-pitting oedema of the skin and oedema of the subcutaneous tissues and mucous membranes.

Angioedema of the face, extremities, lips, tongue, glottis and/or larynx has been reported in patients treated with ACE inhibitors. In such cases, the product should be discontinued promptly and appropriate monitoring instituted to ensure complete resolution of symptoms. In instances when swelling has been confined to the face and lips, the angioedema has generally resolved either without treatment or with antihistamines. Angioedema associated with laryngeal oedema is potentially life-threatening. Where involvement of the tongue, glottis, or larynx is likely to cause airway obstruction appropriate therapy,
including adrenaline and oxygen administration, should be carried out promptly or the patient hospitalised. Patients who respond to medical treatment should be observed carefully for a possible re-emergence of symptoms of angioedema.

There are reports where changing the patient over to another ACE inhibitor was followed by recurrence of oedema and others where it was not. Because of the potential severity of this rare event another ACE inhibitor should not be used in patients with a history of angioedema to a drug of this class (see CONTRAINDICATIONS).

Intestinal angioedema
Intestinal angioedema has been reported rarely in patients treated with ACE-inhibitors. These patients presented with abdominal pain (with or without nausea or vomiting); in some cases there was no prior history of facial angioedema and C-1 esterase levels were normal. The angioedema was diagnosed by procedures including CT scans or ultrasound, or at surgery, and symptoms resolved after stopping the ACE inhibitor. Intestinal angioedema should be included in the differential diagnosis of patients on ACE inhibitors presenting with abdominal pain.

Anaphylactoid reactions during desensitization
Two patients undergoing desensitising treatment with hymenoptera venom while receiving another ACE inhibitor, enalapril, sustained life-threatening anaphylactoid reactions. In the same patients, these reactions were avoided when the ACE inhibitor was temporarily withheld, but they reappeared upon inadvertent rechallenge. Therefore, caution should be used in patients treated with ACE inhibitors undergoing such desensitisation procedures.

Anaphylactoid reactions during high-flux dialysis/lipoprotein apheresis membrane exposure
Patients haemodialysed using high-flux polycrylonitrile ("AN69") membranes are highly likely to experience anaphylactoid reactions if they are treated with ACE inhibitors. Anaphylactoid reactions have also been reported in patients undergoing low density lipoprotein apheresis with dextran sulfate absorption. These combinations should therefore be avoided, either by use of a different class of medication or alternative membranes (eg. cuprophone or polysulphone PSF for haemodialysis).

Neutropenia/Agranulocytosis
Agranulocytosis and bone marrow depression (including leukopenia/neutropenia) have been reported with ACE inhibitors. These have mostly occurred in patients with pre-existing impaired renal function, collagen vascular disease, immunodepressant therapy or a combination of these complicating factors. Most episodes of leukopenia and neutropenia have been single, transient occurrences without any associated clinical symptoms. In addition, data to establish a causal relationship are currently lacking.

It is recommended that periodic monitoring of white blood cell counts should be considered in patients with collagen vascular disease, renal disease (serum creatinine ≥180 µmol/L) and those on multiple drug therapy with agents known to be nephrotoxic or myelosuppressive.

Thiazide diuretics have been also reported rarely to cause agranulocytosis and bone marrow depression.

Hypotension
Fosinopril + hydrochlorothiazide can cause symptomatic hypotension and should be used cautiously in patients receiving concomitant therapy with other anti-hypertensive agents. Symptomatic hypotension is most likely to occur in patients who are volume- and/or salt-depleted as a result of prolonged diuretic therapy, dietary salt restriction, diuresis, diarrhoea, or vomiting. Volume and/or salt depletion should be corrected before initiating therapy with Fosinopril + hydrochlorothiazide. A transient hypotensive response is not a contraindication to further doses, which may be given without difficulty after replacement of salt and/or volume.

In patients with congestive heart failure, with or without associated renal insufficiency, ACE inhibitor therapy may cause excessive hypotension, which may be associated with oliguria, azotemia, and rarely with acute renal failure and death. In such patients Fosinopril + hydrochlorothiazide therapy should be initiated under close medical supervision. Patients should be followed closely for the first two weeks of the treatment and whenever the dose is increased. The antihypertensive effect of thiazide diuretics may be increased in the post sympathectomy patient.
If hypotension occurs, the patient should be placed in a supine position, and, if necessary, treated with intravenous infusion of physiological saline. Fosinopril + hydrochlorothiazide treatment usually can be continued following restoration of blood pressure and volume.

Hepatic Failure
Rarely, ACE inhibitors have been associated with the syndrome that starts with cholestatic jaundice and progresses to fulminant hepatic necrosis and (sometimes) death. The mechanism of this syndrome is not understood. Patients who develop jaundice or marked elevations of hepatic enzymes should discontinue receiving Fosinopril + hydrochlorothiazide and receive appropriate medical attention.

Impaired Hepatic Function
Fosinopril + hydrochlorothiazide should be used with caution in patients with impaired hepatic function or progressive liver disease, since minor alterations of fluid and electrolyte balance may precipitate hepatic coma.

Impaired Renal Function
Fosinopril + hydrochlorothiazide is contraindicated in patients who are anuric. Fosinopril + hydrochlorothiazide is not recommended in patients with severe renal disease (creatinine clearance less than 30 mL/min). The cumulative effects of hydrochlorothiazide and hydrochlorothiazide associated precipitation of azotaemia may occur in some patients with impaired renal function. As a consequence of inhibiting the renin-angiotensin-aldosterone system, changes in renal function may be anticipated in susceptible individuals. In patients with severe congestive heart failure whose renal function may depend on the activity of the renin-angiotensin-aldosterone system, treatment with ACE inhibitors may be associated with oliguria and/or progressive azotemia but rarely with acute renal failure and/or death. In patients with congestive heart failure and pre-existing renal failure, fosinopril like other ACE inhibitors should be used with caution. Although available data suggests minimal accumulation during 10 days therapy with fosinopril 10mg daily, dosage reduction of fosinopril in this patient group may be necessary and hence treatment with Fosinopril + hydrochlorothiazide may be inappropriate. Renal function should be closely monitored.

In hypertensive patients with renal artery stenosis in one or both kidneys, increases in blood urea nitrogen and serum creatinine may occur during treatment with an ACE inhibitor. These increases are usually reversible upon discontinuation of therapy. In such patients, renal function should be monitored during the first few weeks of therapy.

Some hypertensive patients may develop increases in blood urea nitrogen and serum creatinine, usually minor and transient, when fosinopril was given concurrently with a diuretic. This effect is most likely to occur in patients with pre-existing renal impairment. Dosage reduction and/or discontinuation of Fosinopril + hydrochlorothiazide may be required.

Evaluation of the hypertensive patient should always include assessment of renal function (see Dosage and Administration). If deterioration in renal function has occurred after treatment, with one ACE inhibitor, then it is likely to be precipitated by another and in these patients, another class of antihypertensive agent should be preferred.

Electrolyte Imbalance
Determination of serum electrolytes to detect possible electrolyte imbalance should be performed at appropriate intervals.

Thiazides, including HCTZ, can cause fluid or electrolyte imbalance (hypokalemia, hyponatraemia, and hypochloremic alkalosis). Patients should be periodically observed for clinical signs or symptoms of fluid and electrolyte imbalance, such as dryness of mouth, thirst, weakness, lethargy, drowsiness, restlessness, muscle pains or cramps, muscular fatigue, hypotension, oliguria, tachycardia, nausea or vomiting. Although hypokalaemia may develop when thiazide diuretics are used, especially with brisk diuresis or in the presence of severe cirrhosis, concurrent therapy with fosinopril reduces diuretic-induced hypokalaemia. The net effect of Fosinopril + hydrochlorothiazide may be to elevate, reduce or leave serum potassium unchanged. Chloride deficit is generally mild and usually does not require treatment. Calcium excretion is decreased by thiazides. Pathological changes in the parathyroid gland with hypercalcaemia and hypophosphataemia have been observed in a few patients on prolonged thiazide therapy. The common complications of hyperparathyroidism such as renal lithiasis, bone resorption, and
peptic ulceration have not been seen. Thiazides have been shown to increase the urinary excretion of magnesium, which may result in hypomagnesaemia.

**Metabolic Disorders**

Hyperuricaemia and gout may be precipitated by thiazides. Insulin requirements in diabetic patients may be altered and latent diabetes mellitus may become apparent during thiazide administration. Increases in cholesterol and triglyceride levels may be associated with thiazide therapy.

**Cough**

A persistent dry (non-productive) irritating cough has been reported with all ACE inhibitors in use. The frequency of reports has been increasing since cough was first recognised as a side-effect of ACE inhibition. In various studies, the incidence of cough varies between 2% to > 9% depending upon the drug, dosage and duration of use.

The cough is often worse when lying down or at night. The cough is commoner in women (who account for 2/3 of the reported cases). Patients who cough may have increased bronchial reactivity compared to those who do not cough. The observed higher frequency of this complication in non-smokers may be due to higher level of tolerance to cough by smokers.

The mechanism of this adverse reaction is not clear but most likely to be secondary to the effects of converting-enzyme inhibitor on kinins (bradykinin and/or prostaglandin) resulting in stimulation of pulmonary cough reflex. Once a patient has developed intolerable cough, an attempt may be made to switch the patient to another ACE inhibitor. The reaction may recur on rechallenge with another ACE inhibitor but this is not invariably the case. A change in anti-hypertensive regime may be required in severe cases.

**Systemic Lupus Erythematosus**

Thiazide diuretics have been reported to cause exacerbation of systemic lupus erythematosus.

**Surgery/Anaesthesia**

In patients undergoing major surgery or during anaesthesia with agents that produce hypotension, ACE inhibitors may block angiotensin II formation secondary to compensatory renin release and may thus augment the hypotensive response. If hypotension occurs, and is considered to be due to this mechanism, it can be corrected by volume expansion.

**Dermatological Reactions**

Dermatological reactions characterised by maculo-papular pruritic rashes and sometimes photosensitivity has been reported with another ACE inhibitor. Rare and sometimes severe skin reactions (lichenoid eruptions, psoriasis, pemphigus like rash, rosacea, Stevens-Johnson syndrome etc) have been reported. A causal relationship is difficult to assess.

Patients who developed a cutaneous adverse event with one ACE inhibitor may be free of reaction when switched to another drug of the same class, but there are also reports of cross-reactivity.

**Taste Disturbances (Dysgeusia)**

Taste disturbances were reported to be high (up to 12.5%) with high doses of another ACE inhibitor. The actual incidence of taste disturbance is probably low (< 0.5%) but data in this respect is scarce and difficult to interpret.

Taste disturbances with ACE inhibitors are described as suppression of taste or a metallic sensation in the mouth. The dysgeusia occurs usually in the first weeks of treatment and usually disappears within 1-3 months of treatment.

**Use In Pregnancy: (Category “D”)**

As with all ACE inhibitors, APO-Fosinopril HCTZ 10/12.5 mg or APO-Fosinopril HCTZ 20/12.5 mg should not be taken during pregnancy. Pregnancy should be excluded before starting treatment with APO-Fosinopril HCTZ 10/12.5 mg or APO-Fosinopril HCTZ 20/12.5 mg and avoided during treatment.

If a patient intends to become pregnant, treatment with ACE inhibitors must be discontinued and replaced by another form of treatment.
If a patient becomes pregnant while on ACE inhibitors, she must immediately inform her doctor to discuss a change in medication and further management.

When used in pregnancy, ACE inhibitors can cause injury and even death to the developing foetus.

The use of ACE inhibitors during the second and third trimesters of pregnancy has been associated with foetal and neonatal injury including hypotension, neonatal skull hypoplasia anuria, reversible and irreversible renal failure and death.

Oligohydramnios has also been reported, presumably resulting from decreased foetal renal function; oligohydramnios has been associated with foetal limb contractures, craniofacial malformations, hypoplastic lung development, and intrauterine growth retardation. Prematurity and patent ductus arteriosus have also been reported.

A historical cohort study in over 29,000 infants born to non diabetic mothers has shown 2.7 times higher risk for congenital malformations in infants exposed to any ACE inhibitor during 1st trimester compared to no exposure. The risk ratios for cardiovascular and central nervous system malformations were 3.7 times (95% confidence interval 1.89 to 7.3) and 4.4 times (95% confidence interval 11.37 to 14.02) respectively, compared to no exposure.

Use in Lactation
Both fosinopril and hydrochlorothiazide are detectable in breast milk. Because of the potential for serious adverse reactions in breast fed infants from fosinopril and hydrochlorothiazide, a decision should be made whether to discontinue breast feeding or to discontinue APO-Fosinopril HCTZ 10/12.5 mg and APO-Fosinopril HCTZ 20/12.5 mg Tablets, taking into account the importance of fosinopril and hydrochlorothiazide to the treatment of the mother.

Paediatric Use
Safety and effectiveness in children have not been established.

Use in the Elderly
Among patients who received fosinopril/hydrochlorothiazide in clinical studies, 20% were 65 to 75 years old. Overall differences in effectiveness or safety were not observed between these patients and younger patients, however greater sensitivity of some older individuals cannot be ruled out.

Carcinogenicity/ Mutagenicity
At least one other ACE inhibitor has caused an increase in the incidence of oxyphilic renal tubular cells and oncocytomas in rats. The potential to cause this effect with other ACE inhibitors in man is unknown. Moreover, the progression of oxyphilic cells to oncocytomas is rare in humans and when it does occur, it is considered to be benign.

In two-year studies involving both mice and rats at doses up to 400 mg/kg daily, there was no evidence of a carcinogenic effect. Neither fosinopril sodium nor the active fosinopril diacid was mutagenic in the Ames microbial mutagen test, the mouse lymphoma forward mutation assay, or a mitotic gene conversion assay. Fosinopril was also not genotoxic in a mouse micronucleus test in vivo and a mouse bone marrow cytogenetic assay in vivo. In the Chinese hamster ovary cell cytogenic assay, fosinopril increased the frequency of chromosomal aberrations when tested without metabolic activation at a concentration that was toxic to the cells. However, there was no increase in chromosomal aberrations at lower drug concentrations without metabolic activation or at any concentration with metabolic activation.

Effects on fertility
There were no adverse reproductive effects in male and female rats treated with 15 to 60 mg/kg daily. There was no effect on pairing time prior to mating in rats until a daily dose of 240 mg/kg, a toxic dose, was given; at this dose, a slight increase in pairing time was observed.

Interactions with Other Medicines
Alcohol, barbiturates or narcotics: potentiation of thiazide diuretic induced orthostatic hypotension may occur.
Antacids: antacids (aluminium hydroxide, magnesium hydroxide, simethicone) may impair absorption of Fosinopril and hydrochlorothiazide. If concomitant administration of these agents is indicated dosing should be separated by 2 hours.

Antidiabetic drugs (oral agents and insulin): thiazides may elevate blood glucose levels; thus dosage adjustments of antidiabetic agents may be necessary.

Antigout medication: dosage adjustments of antigout medication may be necessary since hydrochlorothiazide may raise the level of blood uric acid. Increase in the dosage of probenecid or sulphinpyrazone may be necessary.

Calcium salts: thiazide diuretics may increase serum calcium levels due to decreased excretion. If calcium must be prescribed, serum calcium levels should be monitored and calcium dosage adjusted accordingly.

Cholestyramine resin and colestipol hydrochloride: may delay or decrease absorption of hydrochlorothiazide. Fosinopril and hydrochlorothiazide should be taken at least one hour before or four to six hours after these medications.

Lithium: increased serum lithium levels and risk of lithium toxicity have been reported in patients receiving ACE inhibitors and/or diuretic agents concomitantly with lithium. Fosinopril and hydrochlorothiazide and lithium should be coadministered with caution and frequent monitoring of serum lithium levels is recommended.

Inhibitors of endogenous prostaglandin synthesis: in some patients, these agents can reduce the effects of diuretics. Indomethacin has been reported to reduce the antihypertensive effect of other ACE inhibitors, especially in cases of low renin hypertension. Other nonsteroidal anti-inflammatory agents (e.g. aspirin) may have a similar effect.

In studies with concomitant administration of aspirin and fosinopril, the AUC for unbound fosinopril diacid was not altered, however the AUC for total (bound and unbound) fosinopril diacid and 48 hour cumulative urinary excretion were reduced by 42%.

Combination use of ACE inhibitors or angiotensin receptor antagonists, anti-inflammatory drugs and thiazide diuretics: The use of an ACE inhibiting drug (ACE- inhibitor or angiotensin receptor antagonists), an anti-inflammatory drug (NSAID, including COX-2 inhibitor) and a thiazide diuretic at the same time increases the risk of renal impairment. This includes use in fixed-combination products containing more than one class of drug. Combined use of these medications should be accompanied by increased monitoring of serum creatinine, particularly at institution of the combination. The combination of drugs from these three classes should be used with caution particularly in elderly patients and in those with pre-existing renal impairment.

Other diuretics and antihypertensive medications: potassium-sparing diuretics (e.g amiloride, spironolactone, triamterene) or potassium supplements can increase the risk of hyperkalaemia. If concomitant use of Fosinopril and hydrochlorothiazide and such agents is indicated, they should be given with caution, and the patients serum potassium monitored frequently.

With potassium supplements and salt substitutes: These supplements and salt substitutes should be used with caution and serum potassium should be monitored frequently.

Drugs used during surgery: the effects of nondepolarizing muscle relaxants, preanaesthetics and anaesthetics used during surgery (e.g. tubocurarine chloride and gallamine triethiodide) may be potentiated by hydrochlorothiazide and dosage adjustments may be required. Fluid and electrolyte imbalances should be monitored and corrected prior to surgery. Caution should be used in patients taking Fosinopril and hydrochlorothiazide and pressor agents (e.g. noradrenaline) who undergo surgery. Preanaesthetic and anaesthetic agents should be given in reduced dosage and if possible hydrochlorothiazide therapy discontinued one week prior to surgery.

Other agents: the bioavailability of fosinopril diacid is not altered by coadministration with cimetidine, digoxin, metoclopramide, nifedipine, propanolol, propantheline or warfarin.
Laboratory test interaction: Fosinopril may cause a false low measurement of serum digoxin levels with assays utilising the charcoal absorption method. Other kits, which utilise the antibody coated-tube method, may be used instead. Therapy with Fosinopril and hydrochlorothiazide should be interrupted for a few days before carrying out tests of parathyroid function.

ADVERSE EFFECTS

Adults

Clinical Trials

Adverse events in patients receiving Fosinopril and hydrochlorothiazide were generally mild and transient and similar to those seen with the individual components taken separately. The incidence and type of adverse events in the elderly (≥ 65 years) were similar to those seen in younger.

Table A displays the adverse events reported among subjects in active- and placebo-controlled clinical trials of combination fosinopril/hydrochlorothiazide. It includes only those adverse events reported with an incidence of 1.0% or greater in subjects receiving Fosinopril and hydrochlorothiazide 10/12.5 mg or Fosinopril and hydrochlorothiazide 20/12.5 mg.

<sup>a</sup> Indicates a significantly lower incidence compared to the placebo group at p ≤ 0.05

<sup>b</sup> Indicates a significantly greater incidence compared to the placebo group at p ≤ 0.05

In placebo-controlled clinical trials, the usual duration of therapy was two months.
Discontinuations due to any clinical or laboratory adverse event were 3.5% and 4.3% in fosinopril/HCTZ-treated and placebo-treated patients, respectively. If the total clinical trial population is considered, withdrawals due to adverse events or laboratory abnormalities occurred in 2.6% of fosinopril/HCTZ-treated patients, 2.7% of fosinopril-treated patients, 2.7% of HCTZ-treated patients and 3.5% of placebo-treated patients.

The following adverse drug reactions, possibly or more strongly associated causally with the use of fosinopril/hydrochlorothiazide, were also reported during clinical trials. The asterisk indicates adverse reactions that occurred in one (1) patient only. The listing does not include events already presented in Table A.

**Cardiovascular**
Uncommon: oedema lower extremity, cardiac rhythm disturbance, subjective rhythm disturbance, ventricular rhythm disturbance, flushing, orthostatic hypotension, hypertension, non-angina cardiac chest pain, oedema and syncope.

**Dermatological**
Uncommon: acne, dermatitis, ecchysis, extremity erythema, bacterial skin infection pruritus, rash and skin discomfort.

**Endocrine/Metabolic**
Uncommon: breast disorder, hot flashes, libido change, menstrual disorder and polydipsia.

**Gastrointestinal**
Uncommon: abnormal stool, constipation, decreased appetite, diarrhoea, abdominal distension, dry mouth, eructation, GI polyp excision, gastritis, increased appetite, oral lesion, intestinal obstruction, and abdominal pain.

**General**
Uncommon: chest pain, chills, cold sensation, fever, halitosis, hyperhydrosis, malaise and weight loss.

**Hepatic/Biliary**
Uncommon: hepatitis

**Immunological**
Uncommon: allergy and angioedema.

**Musculoskeletal**
Uncommon: limitation of movement, muscle cramp, musculoskeletal trauma, musculoskeletal chest pain, extremity swelling, tendonitis and extremity weakness.

**Nervous System**
Uncommon: depression, neuropathy entrapment, memory impairment, numbness, somnolence, emotional lability/disturbance, insomnia, and paresthesia.

**Renal/Genitourinary**
Uncommon: abnormality urination, prostate disorder and vaginal bleeding.

**Respiratory**
Uncommon: congestion, subjective disorder of upper airway, dyspnea, epistaxis, sneezing.

**Special Senses**
Uncommon: bad taste of medication, ear abnormality, ear infection and hearing abnormality.

**Laboratory Test Abnormalities**
Serum electrolytes, uric acid, glucose, magnesium, cholesterol, triglycerides and calcium (See PRECAUTIONS). Neutropenia, decreased haematocrit and haemoglobin, eosinophilia, elevated creatinine or BUN.
Other adverse events reported when fosinopril or HCTZ is taken separately include:

**Cardiovascular**
Sudden death, cardiac/respiratory arrest, shock, hypertensive crisis, peripheral vascular disease/claudication, angina/myocardial infarct, cerebrovascular accident, hypotension, conduction disorder, and palpitations.

**Dermatologic**
Urticaria, and photosensitivity

**Endocrine/Metabolic**
Diabetes mellitus, and gout.

**Foetal/Neonatal Morbidity and Mortality**
The use of ACE inhibitors during pregnancy has been associated with foetal and neonatal injury, including hypotension, neonatal skull hypoplasia, anuria, reversible or irreversible renal failure, and death. Oligohydramnios has also been reported, presumably resulting from decreased foetal renal function; oligohydramnios in this setting has been associated with foetal limb contractures, craniofacial deformation, and hypoplastic lung development. Prematurity, intrauterine growth retardation, and patent ductus arteriosus have also been reported. More recently, prematurity, patent ductus arteriosus and other structural cardiac malformations, as well as neurologic malformations, have been reported following exposure limited to the first trimester of pregnancy. (see PRECAUTIONS- Use in Pregnancy)

**Gastrointestinal**
Bleeding, pancreatitis, tongue swelling, dysphagia, anorexia, weight change, pyrosis, sialoadenitis, and flatulence.

**General**
Pain and xanthopsia.

**Hepatic/Biliary**
Jaundice (cholestatic), and/or liver enzyme abnormalities.

**Hematologic**
Aplastic anemia, megaloblastic anaemia, agranulocytosis, leukopenia, thrombocytopenia, purpura, hemolytic anemia, lymphadenopathy.

**Immunologic:**
necrotizing angitis, Stevens-Johnson Syndrome, respiratory distress (including pneumonitis and pulmonary oedema), fever, anaphylaxis and toxic epidermal necrolysis (see also Dermatologic).

**Musculoskeletal**
Arthralgia, arthritis, and myalgia.

**Nervous/Psychiatric**
Lightheadedness, memory disturbance, drowsiness, confusion, behaviour change, mood change, tremor, sleep disturbance, cerebral infarction, transient ischaemic attack, and restlessness.

**Respiratory:** bronchospasm, pneumonia, pulmonary congestion, laryngitis/hoarseness, sinusitis, and pleuritis. A symptom complex of cough, bronchospasm, eosinophilia has been observed in two patients treated with fosinopril.

**Renal/Genitourinary**
Impotence, acute renal failure, renal insufficiency, interstitial nephritis, renal stones, abnormal urinary sediment.

**Special Senses**
Taste disturbances, eye disturbances - other, transient blurred vision, vision disturbances, ear pain and tinnitus.
Among other potential adverse effects reported with ACE Inhibitors, psychiatric reactions such as hallucinations (especially visual) have been reported with the use of ACE inhibitors.

**DOSAGE AND ADMINISTRATION**

**Adults including the elderly**
The usual dose is one APO-Fosinopril HCTZ 10/12.5 mg or APO-Fosinopril HCTZ 20/12.5 mg (Fosinopril + Hydrochlorothiazide tablets 10 + 12.5 mg or Fosinopril + Hydrochlorothiazide tablets 20 + 12.5 mg Tablets) once daily.

**Children (< 18 years)**
The safety and efficacy of APO-Fosinopril HCTZ 10/12.5 mg and APO-Fosinopril HCTZ 20/12.5 mg has not been established.

**Hepatic impairment**
The usual dose of APO-Fosinopril HCTZ 10/12.5 mg or APO-Fosinopril HCTZ 20/12.5 mg is recommended in patients with mild to moderate hepatic impairment (See **PRECAUTIONS**)

**Renal impairment**
The usual dose of APO-Fosinopril HCTZ 10/12.5 mg or APO-Fosinopril HCTZ 20/12.5 mg is recommended for patients with mild to moderate renal impairment (creatinine clearance > 30 mL/min, serum creatinine approximately ≤ 265 µmol/L). Fosinopril and hydrochlorothiazide is not recommended for patients with severe renal dysfunction (creatinine clearance < 30 mL/min) since loop diuretics are preferred to thiazides in these patients (See **PRECAUTIONS**).

**OVERDOSAGE**
No specific information is available on the treatment of overdose with fosinopril and hydrochlorothiazide; treatment should be symptomatic and supportive. Therapy with fosinopril and hydrochlorothiazide should be discontinued and the patient closely monitored. Suggested measures include administration of activated charcoal and correction of dehydration, electrolyte imbalance and hypotension by established procedures. Fosinopril is poorly removed from the body by haemodialysis or peritoneal dialysis. The degree to which hydrochlorothiazide is removed by haemodialysis has not been established.

**Contact the Poison Information Centre on 13 11 26 (Australia) for advice on the management of overdose.**
PRESENTATION AND STORAGE CONDITIONS

APO-Fosinopril HCTZ 10/12.5 mg is available as white to off-white, circular tablets, debossed with ‘RC3’ on one side and plain on the other side, containing 10 mg of Fosinopril Sodium and 12.5mg of Hydrochlorothiazide.

APO-Fosinopril HCTZ 20/12.5 mg is available as White to off-white, flat beveled edged, circular tablets, debossed with ‘FH1’ on one side and plain on the other side, containing 20 mg of Fosinopril Sodium and 12.5mg of Hydrochlorothiazide.

The tablets are supplied in a blister pack containing 30 tablets.

Store below 25º C – Protect from moisture.
