Name of the drug
Cisplatin

Description
Cisplatin Injection is a sterile, isotonic, preservative free solution containing Cisplatin USP 1mg/mL, Sodium Chloride BP and Mannitol BP in Water for Injections BP.

Pharmacology
Class: Antineoplastic agent.
Mechanism of action: Cisplatin is a platinum compound of which only the cis-isomer is active. It appears to produce intra- and interstrand cross links which modify DNA structure and inhibit DNA synthesis. In addition, and to a lesser extent, cisplatin inhibits protein and RNA synthesis. It does not appear to be phase-specific in the cell cycle.

Pharmacokinetics:
Distribution: Cisplatin seems to concentrate in the liver, kidneys, small intestine and testes. It does not cross the blood brain barrier so does not penetrate the cerebrospinal fluid (CSF) to any great extent. CSF levels of cisplatin are low although significant amounts can be detected in intracerebral tumours. Animal studies show good uptake into ovarian and uterine tissue.
Elimination and Excretion: After IV injection, plasma decay is biphasic. The initial phase is rapid with a half-life of 25-49 minutes and this is followed by a prolonged elimination phase with a half-life of 2-4 days. This long elimination phase is probably due to a high degree of protein binding. Normally more than 90% is bound to plasma proteins, but this may be more during a slow infusion. Excretion is predominantly renal. About 15-25% of a dose is rapidly excreted, mainly as intact drug, in the first 2-4 hours and 20-75% in the first 24 hours. The remainder represents drug bound to tissues or plasma proteins.

Indications
Cisplatin Injection may be used singularly or in combination with other chemotherapeutic agents in the treatment of:
- Metastatic nonseminomatous germ cell carcinoma
- Advanced stage, refractory ovarian carcinoma
- Advanced stage, refractory bladder carcinoma
- Refractory squamous cell carcinoma of the head and neck

Contraindications
Cisplatin Injection is contraindicated in the following conditions:
- Renal impairment
- Hearing disorders
- Bone marrow depression
- During pregnancy or lactation
- In patients with a history of hypersensitivity to cisplatin or platinum containing compounds.

Precautions
Cisplatin should be administered only under constant supervision by physicians experienced in therapy with cytotoxic agents and only when potential benefits of cisplatin therapy outweigh the possible risks. Appropriate facilities should be available for adequate management of complications should they arise.
To minimise the risk of nephrotoxicity, hydrate before, during and after therapy (see Dosage and Administration). Prior to initial therapy, then before subsequent doses, the following parameters should be monitored: renal function including Glomerular Filtration Rate (GFR), Blood Urea Nitrogen (BUN), serum creatinine and creatinine clearance; electrolytes to detect hypomagnesaemia or...
hypocalcaemia; auditory function; red blood cells, white blood cells and platelets; liver function and neurological status.

- **Nephrotoxicity:** Cumulative and dose-related renal insufficiency is the major dose-limiting toxicity of cisplatin. The most commonly observed changes are a fall in GFR reflected by a rise in serum creatinine and a reduction in effective renal plasma flow. Pre and post treatment hydration may reduce nephrotoxicity (see **Dosage and Administration**). Renal function must return to normal before further doses are given.

- **Myelosuppression:** Haematological toxicity is dose-related and cumulative. The lowest levels of circulating platelets and leucocytes generally occur between 18-23 days (range 7.3-45) with most patients recovering after 39 days (range 13-62). Leucopenia and thrombocytopenia are more pronounced at doses greater than 50mg/m$^2$. Subsequent courses of cisplatin should not be instituted until platelets are present at levels greater than 100,000/mm$^3$ and white cells greater than 4,000/mm$^3$.

- **Anaemia:** Anaemia (decrease of greater than 2g % haemoglobin) occurs in a significant number of patients, usually after several courses of treatment. Transfusions of packed red cells may be necessary in severe cases. A Coombs’ positive haemolytic anaemia has been reported with cisplatin. Further courses with cisplatin in sensitised individuals may cause increased haemolysis.

- **Nausea and Vomiting:** Marked nausea and vomiting occur in almost all patients treated with cisplatin and are occasionally so severe that dosage reduction or discontinuance of treatment is necessary.

- **Ototoxicity:** Ototoxicity is cumulative and occurs mainly with high dose regimes. Tinnitus or occasional decreased ability to hear normal conversation are indications of ototoxicity, which have been frequently observed. Tinnitus is usually transient lasting from a few hours to a week after cessation of therapy. Hearing loss is usually unilateral or bilateral and occurs in the 4000 to 8000 Hz range. Frequency and severity of these hearing disorders increases with repeated doses and severe impairment may not be reversible. Auditory function should be monitored to avoid these symptoms of ototoxicity.

- **Hypomagnesaemia and hypocalcaemia:** Hypomagnesaemia occurs frequently and is probably due to renal tubular damage leading to wasting of magnesium ions. Secondary hypocalcaemia may occur with resulting tetany. Monitoring of electrolytes is necessary.

- **Neurotoxicity:** Peripheral neuropathy, postural hypotension, myasthenic syndromes, seizures and visual loss may occur especially after prolonged cisplatin treatment. Cessation of cisplatin is recommended if these symptoms occur.

- **Anaphylaxis:** Occasionally reactions secondary to cisplatin therapy have been reported. Patients receiving cisplatin should be observed carefully for possible anaphylactic like reactions and the necessary equipment and medication should be readily available to treat such reactions. Patients with a family history of atopy are at particular risk.

**Use in Pregnancy:** Category D. Cisplatin has been shown to be mutagenic in bacterial cultures and produces chromosome aberrations in animal cells in tissue culture. In mice cisplatin is teratogenic and embryotoxic, and its use in pregnant women is not recommended. Women of childbearing potential should use adequate contraception and cisplatin should only be used if the potential benefits outweigh the risk of therapy. If the patient becomes pregnant whilst receiving the drug she should be advised of the hazard to the fetus.

**Use in Lactation:** It is not known whether cisplatin is excreted in breast milk. However, because of the potential risk to the newborn it is recommended that breastfeeding be discontinued during therapy with cisplatin in lactating women.

**Interactions with other drugs:** Potentially nephrotoxic and ototoxic drugs such as aminoglycoside antibiotics or loop diuretics may exacerbate the nephrotoxic and ototoxic effects of cisplatin. Live vaccines should not be used in patients undergoing Cisplatin therapy.
Cisplatin interacts with aluminium to form a black precipitate. Needles, syringes, catheters or IV administration sets that contain aluminium should not be used for the administration of cisplatin.

**Adverse Effects**

- **Gastrointestinal Disorders:** Severe nausea and vomiting usually begin 1-4 hours after treatment and may persist for up to a week. This may necessitate stopping treatment. These side effects are only partially relieved by standard antiemetics. Reported toxicity includes gingival platinum line.

- **Renal and Urinary Disorders:** Acute renal toxicity, which was highly frequent in the past and represented the major dose-limiting toxicity of cisplatin, has been greatly reduced by the use of 6 to 8 hour infusions as well as by concomitant intravenous hydration and forced diuresis. Cumulative toxicity, however, remains a problem and may be severe. Renal impairment, which is associated with tubular damage, may first be noted during the second week after a dose and is manifested by an increase in serum creatinine, BUN, serum uric acid and/or decrease in creatinine clearance. Renal insufficiency is generally mild to moderate and reversible at the usual doses of the drug, however, high or repeated doses can increase the severity and duration of renal impairment and may produce irreversible renal insufficiency (sometimes fatal). Renal failure has been reported following intraperitoneal instillation of the drug.

- **Blood and Lymphatic System Disorders:** Mild bone marrow toxicity may occur with both leucopenia and thrombocytopenia. These effects are usually reversible after ceasing treatment. Cisplatin may also induce anaemia: this is not clearly dose related and is occasionally caused by haemolysis.

- **Immune System Disorders:** Anaphylactic and anaphylactic like reactions such as flushing, facial oedema, wheezing, tachycardia, and hypotension have been reported in patients previously exposed to Cisplatin. The reactions usually occur within a few minutes of cisplatin administration and may be controlled with IV adrenaline, corticosteroids and/or antihistamines.

- **Ear and Labyrinth Disorders:** Unilateral or bilateral tinnitus and/or hearing loss in high frequencies (>4000Hz) may occur in 10% of patients and is usually reversible. The damage to the hearing system appears to be dose related and cumulative, and it is reported more frequently in very young or very old patients. Auditory function should be monitored more closely during treatment.

- **Nervous System Disorders:** Peripheral neuropathies occur infrequently with usual doses of the drug. They are generally sensory in nature (e.g. paraesthesia of the upper and lower extremities), but can also include motor difficulties, reduced or absent reflexes and leg weakness. Autonomic neuropathy, seizures, slurred speech, loss of taste and memory loss have also been reported. These neuropathies usually appear after prolonged therapy, but have also developed after a single drug dose. Areflexia and loss of proprioception and vibratory sensation may be seen, especially if cisplatin is given at higher doses or more frequently than recommended. In some patients they may be irreversible however, they have been partially or completely reversible in others following discontinuance of cisplatin therapy. Cerebrovascular accident has been reported in patients treated with cisplatin.

- **Eye Disorders:** Retinal toxicity manifests as blurred vision and altered colour perception. Optic neuritis, papilloedema and cortical blindness have been reported rarely following the administration of cisplatin. These events are usually reversible after drug withdrawal.

- **Cardiac Disorders:** Cardiovascular abnormalities (coronary disease, congestive heart failure, arrhythmias, postural hypotension, thrombotic microangiopathy etc).

- **Respiratory, Thoracic and Mediastinal Disorders:** Pulmonary toxicity has been reported in patients treated with cisplatin in combination with bleomycin or 5-fluorouracil.

- **Hepatobiliary Disorders:** Mild and transient elevations of serum AST and ALT levels may occur infrequently.

- **Skin and Subcutaneous Tissue Disorders:** Mild alopecia. Rarely, urticarial or maculopapular skin rashes have also been observed.

- **Musculoskeletal and Connective Tissue Disorders:** Myalgia.
Reproductive System and Breast Disorders: Cisplatin can affect male fertility. Impairment of spermatogenesis and azoospermia have been reported. Although the impairment of spermatogenesis can be reversible, males undergoing cisplatin treatment should be warned about the possible adverse effects on male fertility.

Metabolism and Nutrition Disorders: Cisplatin may also cause serious electrolyte disturbances, mainly represented by hypomagnesaemia, hypocalcaemia, and hypokalaemia, and associated with renal tubular dysfunction. Hypomagnesia and/or hypocalcaemia may become symptomatic, with muscle irritability or cramps, clonus, tremor, carpopedal spasm and/or tetany. Other reported toxicities are hyperuricaemia, hyponatremia and syndrome of inappropriate antidiuretic hormone (SIADH). Allopurinol may be administered to reduce serum uric acid levels.

General Disorders and Administration Site Conditions: Pyrexia, local effects such as phlebitis, cellulitis and skin necrosis (following extravasation of the drug) may also occur.

Dosage and Administration

Adult and Children Single Agent Therapy

Typical doses and schedules are:
50-100mg/m² as a single IV infusion every 3-4 weeks over 6-8 hours; or slow IV infusion of 15-20mg/m²/day for 5 days, every 3-4 weeks.

Dosage should be reduced in patients with depressed bone marrow function.

Combination Therapy

Cisplatin is commonly used in combination therapy with the following cytotoxic agents:
- treatment of testicular cancer: vinblastine, bleomycin, actinomycin D;
- treatment of ovarian cancer: cyclophosphamide, doxorubicin, hexamethylmelamine, 5-fluorouracil;
- treatment of head and neck cancer: bleomycin, methotrexate.

Subsequent Treatment With Cisplatin

A repeat course of cisplatin should not be given until:

- the serum creatinine is below 140micromol/L and/or the plasma urea is below 9mmol/L and
- circulating blood elements are at an acceptable level (platelets at least 100,000/mm³, WBC at least 4000/mm³).

A base line audiogram should be taken and the patient monitored periodically for auditory deterioration (see Precautions).

Impaired Hepatic Function: Human studies show a high uptake of cisplatin in the liver. Elevated aspartate aminotransferase (AST) and alkaline phosphatase with clinical signs of liver toxicity have been reported. Cisplatin should be used with caution in patients with pre-existing hepatic dysfunction.

Impaired Renal Function: Cisplatin displays high tissue uptake in the kidneys and exhibits dose related and cumulative nephrotoxicity. It is excreted mainly in the urine. The plasma elimination half-life of cisplatin is prolonged and plasma levels are markedly elevated in renal function. Caution should be exercised in patients with pre-existing renal dysfunction. Cisplatin is contraindicated in patients with serum creatinine levels greater than 200micromol/L. Repeat courses are not advised until serum creatinine is below 140micromol/L and/or blood urea below 9mmol/L.

Administration: Patients should be adequately hydrated before and for 24 hours following administration of cisplatin to ensure good urinary output and minimise nephrotoxicity.

Pretreatment Hydration: Hydration may be achieved by intravenous infusion of 2 litres of 5% glucose in ½ to 1/3 normal saline infused over a 2-4 hour period.

Administration: Cisplatin Injection may be added to 1 litre of normal saline and infused over the desired time period.

Post-treatment Hydration: It is important to maintain adequate hydration and urinary output for 24 hours following the infusion.

The product and its admixtures contain no antimicrobial agent. In order to reduce microbiological hazards it is recommended that further dilution be effected immediately prior to use and infusion.
commenced as soon as practicable after preparation of the admixture. Infusion should be completed within 24 hours of preparation and the residue discarded.

**Overdosage**
Treat symptomatically. See **Adverse Effects** for possible complications.

**Handling precautions**
As with all antineoplastic agents, trained personnel should prepare Cisplatin Injection. This should be performed in a designated area (preferably a cytotoxic laminar flow cabinet). Protective gown, mask, gloves and appropriate eye protection should be worn while handling cisplatin. Where solution accidentally contacts skin or mucosa, the affected area should be immediately washed thoroughly with soap and water. It is recommended that pregnant personnel not handle cytotoxic agents such as cisplatin.

Luer-Lock fitting syringes are recommended. Large bore needles are recommended to minimise pressure and possible formation of aerosols. Aerosols may also be reduced by using a venting needle during preparation.

Items used to prepare cisplatin, or articles associated with body waste should be disposed of by placing in a double sealed polythene bag, and incinerating at 1100°C.

**Spills and disposal**
If spills occur, restrict access to the affected area. Wear two pairs of gloves (latex rubber), a respiratory mask, a protective gown and safety glasses. Limit the spread of the spill by covering with a suitable material such as absorbent towel or adsorbent granules. Spills may also be treated with 5% sodium hypochlorite. Collect up absorbent/adsorbent material and other debris from spill and place in a leak proof plastic container and label accordingly.

Cytotoxic waste should be regarded as hazardous or toxic and clearly labelled ‘CYTOTOXIC WASTE FOR INCINERATION AT 1100°C’. Waste material should be incinerated at 1100°C for at least 1 second. Cleanse the remaining spill area with copious amounts of water.

**Presentation**
AUST R 11349: Cisplatin Injection 10mg in 10mL (sterile) Plastic Vial (5’s).
AUST R 11349: Cisplatin Injection 10mg in 10mL (sterile) Plastic Vial (single vial).
AUST R 49301: Cisplatin Injection 50mg in 50mL (sterile) Plastic Vial.
AUST R 49302: Cisplatin Injection 100mg in 100mL (sterile) Plastic Vial.

**Storage**
Store between 15-25ºC. Do not refrigerate. Protect from light. Single use only. Discard unused portion.

The expiry date (month/year) is stated on the package after EXP.

**Poison schedule**
Australia – S4.
