PRODUCT INFORMATION
DALACIN® C Phosphate
Clindamycin Injection
For Intramuscular and Intravenous Use

DESCRIPTION

DALACIN C Phosphate (clindamycin phosphate injection) is a sterile solution of a water soluble ester of clindamycin and phosphoric acid which contains the equivalent of 150 mg clindamycin base, 9.45 mg benzyl alcohol and 0.5 mg disodium edetate in each mL of water for injections. Clindamycin is a semi-synthetic antibiotic produced by a 7(S)-chloro-substitution of the 7(R)-hydroxyl group of the parent compound lincomycin.

The MW of clindamycin phosphate is 504.96 and its structural formula is represented below:

![Chemical Structure]

CAS Number: 24729-96-2

ACTION

Microbiology

Although clindamycin phosphate is inactive in vitro, rapid in vivo hydrolysis converts this compound to the antibacterially active clindamycin.

Clindamycin has been shown to have in vitro activity against isolates of the following organisms:

- Aerobic gram-positive cocci, including:
  - Staphylococcus aureus
  - Staphylococcus epidermidis (penicillinase and non-penicillinase producing strains)
    - When tested by in vitro methods some staphylococcal strains, originally resistant to erythromycin, rapidly develop resistance to clindamycin.
  - Streptococci (not Enterococcus faecalis)
  - Pneumococci
Anaerobic gram-negative bacilli, including:

*Bacteroides* species
*Fusobacterium* species

Anaerobic gram-positive non-spore forming bacilli, including:

*Propionibacterium*
*Eubacterium*
*Actinomyces* species

Anaerobic and microaerophilic gram-positive cocci, including:

*Peptococcus* species
*Peptostreptococcus* species
Microaerophilic *streptococci*
*Clostridia*

*Clostridia* are more resistant than most anaerobes to clindamycin. Most *C. perfringens* are susceptible, but other species, e.g. *C. sporogenes* and *C. tertium* are frequently resistant to clindamycin.

Susceptibility testing should be done.

Cross-resistance has been demonstrated between clindamycin and lincomycin.

**Disc Susceptibility Testing**

Dilution or diffusion techniques – either quantitative (MIC) or breakpoint, should be used following a regularly updated, recognised and standardised method (e.g. NCCLS). Standardised susceptibility testing procedures require the use of laboratory control microorganisms to control the technical aspects of laboratory procedures.

A report of “Susceptible” indicates that the pathogen is likely to be inhibited if the antimicrobial compound in the blood reaches the concentrations usually achievable. A report of “Intermediate” indicates that the result should be considered equivocal, and if the microorganism is not fully susceptible to alternative, clinically feasible drugs, the test should be repeated. This category implies possible clinical applicability in body sites where the drug is physiologically concentrated or in situations where high dosage of drug can be used. This category also provides a buffer zone, which prevents small, uncontrolled technical factors from causing major discrepancies in interpretation. A report of “Resistant” indicates that the pathogen is not likely to be inhibited if the antimicrobial compound in the blood reaches the concentrations usually achievable and other therapy should be selected.

The prevalence of resistance may vary geographically for selected species and local information on resistance is desirable, particularly when treating severe infections.

**HUMAN PHARMACOLOGY**

Biologically inactive clindamycin phosphate is rapidly converted to active clindamycin.
By the end of short-term intravenous infusion, peak serum levels of active clindamycin are reached. Biologically-inactive clindamycin phosphate disappears rapidly from the serum, the average disappearance half-life is 6 minutes; however, the serum disappearance half-life of active clindamycin is about 3 hours in adults and 2.5 hours in children.

After intramuscular injection of DALACIN C Phosphate, peak levels of active clindamycin are reached within 3 hours in adults and 1 hour in children. Serum level curves may be constructed from IV peak serum levels as given in Table 1 by application of the disappearance half-lives listed above.

Serum levels of clindamycin can be maintained above the in vitro minimum inhibitory concentrations for most indicated organisms by administration of DALACIN C Phosphate every 8-12 hours in adults and every 6-8 hours in children, or by continuous intravenous infusion. An equilibrium state is reached by the third dose.

The disappearance half-life of clindamycin is increased slightly in patients with markedly reduced renal or hepatic function; dosage schedules need not be modified in the presence of mild to moderate renal or hepatic disease. No significant levels of clindamycin are attained in the cerebrospinal fluid even in the presence of inflamed meninges.

Serum assays for active clindamycin require an inhibitor to prevent in vitro hydrolysis of clindamycin phosphate.

Table 1: Average Peak Serum Concentrations After Dosing with DALACIN® C Phosphate

* Data in this group from patients being treated for infection
INDICATIONS

DALACIN C Phosphate is indicated in the treatment of serious infections caused by susceptible anaerobic bacteria.

DALACIN C Phosphate is also indicated in the treatment of serious infections due to susceptible strains of streptococci, pneumococci and staphylococci.

Its use should be reserved for penicillin-allergic patients or other patients for whom, in the judgement of the physician, a penicillin is inappropriate.

Anaerobes

Serious respiratory tract infections such as empyema, anaerobic pneumonitis and lung abscess; serious skin and skin structure infections; septicaemia; intra-abdominal infections such as peritonitis and intra-abdominal abscess (typically resulting from anaerobic organisms resident in the normal gastrointestinal tract) and infections of the female pelvis and genital tract such as endometritis, non-gonococcal tubo-ovarian abscess, pelvic cellulitis and post-surgical vaginal cuff infection, all when given in conjunction with an antibiotic of appropriate gram-negative aerobic spectrum.

Streptococci

Serious respiratory tract infections; serious skin and skin structure infections; septicaemia.

Staphylococci

Serious respiratory tract infections; serious skin and skin structure infections; septicaemia; acute haematogenous osteomyelitis.

Pneumococci

Serious respiratory tract infections.

Adjunctive Therapy

In the surgical treatment of chronic bone and joint infections due to susceptible organisms.

Indicated surgical procedures should be performed in conjunction with antibiotic therapy. Bacteriological studies should be performed to determine the causative organisms and their susceptibility to clindamycin.

CONTRAINDICATIONS

This drug is contraindicated in individuals with a history of hypersensitivity to preparations containing clindamycin, lincomycin or any of the ingredients listed under DESCRIPTION.
**PRECAUTIONS**

SERIOUS ANAPHYLACTOID REACTIONS REQUIRE IMMEDIATE EMERGENCY TREATMENT WITH ADRENALINE, OXYGEN AND INTRAVENOUS CORTICOSTEROIDS SHOULD ALSO BE ADMINISTERED AS INDICATED.

This product contains benzyl alcohol. Benzyl alcohol has been reported to be associated with a fatal "Gasping Syndrome" in premature infants.

The use of clindamycin can lead to the development of severe colitis. Fatalities have been reported. Therefore, DALACIN C Phosphate should be reserved for serious infections where less toxic antimicrobial agents are inappropriate, as described in the INDICATIONS section. It should not be used in patients with non-bacterial infections such as most upper respiratory tract infections.

A toxin produced by *Clostridium difficile* appears to be the primary cause. The severity of the colitis may range from mild to life threatening. It is important to consider this diagnosis in patients who develop diarrhoea or colitis in association with the use of antibiotics, including parenteral clindamycin. Symptoms may occur up to several weeks after cessation of antibiotic therapy.

Mild cases of pseudomembranous colitis usually respond to drug discontinuation alone, however in moderate to severe cases appropriate therapy with suitable oral antibacterial agents effective against *Clostridium difficile* should be considered. Fluids, electrolytes and protein replacement should be provided when indicated.

Antibiotic-associated colitis and diarrhoea (due to *C. difficile*), occur more frequently and may be more severe in debilitated and/or elderly patients (> 60 years). When clindamycin is indicated in these patients, they should be carefully monitored for change in bowel frequency.

*Clostridium difficile* associated diarrhoea (CDAD) has been reported with use of nearly all antibacterial agents, including clindamycin, and may range in severity from mild diarrhoea to fatal colitis. Treatment with antibacterial agents alters the normal flora of the colon leading to overgrowth of *C. difficile*.

*C. difficile* produces toxins A and B which contribute to the development of CDAD. Hypertoxin producing strains of *C. difficile* cause increased morbidity and mortality, as these infections can be refractory to antimicrobial therapy and may require colectomy. CDAD must be considered in all patients who present with diarrhoea following antibiotic use. Careful medical history is necessary since CDAD has been reported to occur over two months after the administration of antibacterial agents.

DALACIN C Phosphate should be prescribed with caution in individuals with a history of gastrointestinal disease, particularly colitis.

DALACIN C Phosphate should be used with caution in patients with a history of regional enteritis, ulcerative colitis or antibiotic associated colitis.

DALACIN C Phosphate should be prescribed with caution in atopic individuals.
During prolonged therapy periodic liver and kidney function tests and blood counts should be performed.

Patients with very severe renal disease and/or very severe hepatic disease accompanied by severe, metabolic aberrations should be dosed with caution, and serum clindamycin levels monitored during high-dose therapy.

Indicated surgical procedures should be performed in conjunction with antibiotic therapy. The use of DALACIN C Phosphate may result in overgrowth of non-susceptible organisms - particularly yeasts. Should superinfections occur, appropriate measures should be taken as indicated by the clinical situation.

DALACIN C Phosphate should not be injected intravenously undiluted as a bolus, but should be infused over at least 10-60 minutes as directed in the DOSAGE AND ADMINISTRATION section. Drugs which delay peristalsis (e.g. opiates and diphenoxylate with atropine [LOMOTIL®]) may prolong and/or worsen the condition and should not be used.

**Use in Pregnancy - Category A**

Clindamycin crosses the placenta in humans. After multiple doses, amniotic fluid concentrations were approximately 30% of maternal concentrations. Clindamycin should be used in pregnancy only if clearly needed.

**Usage in the Newborn and Infants**

When DALACIN C Phosphate is administered to newborns and infants, appropriate monitoring of organ system functions is desirable.

**Use in Lactation**

Clindamycin has been reported to appear in breast milk in ranges of 0.7 to 3.8 micrograms/mL. Therefore, it is not recommended for nursing mothers.

**Usage in Meningitis**

Since clindamycin does not diffuse adequately into the cerebrospinal fluid, the drug should not be used in the treatment of meningitis.

**Interactions with Other Drugs**

Clindamycin has been shown to have neuromuscular blocking properties that may enhance the action of other neuromuscular blocking agents. Therefore, it should be used with caution in patients receiving such agents.

Antagonism has been demonstrated between DALACIN C Phosphate and erythromycin *in vitro*. Because of possible clinical significance these two drugs should not be administered concurrently.
See Compatibility/Incompatibility section under DOSAGE AND ADMINISTRATION for physicochemical interactions.

**ADVERSE REACTIONS**

The following adverse reactions have been reported with the use of clindamycin.

**Gastrointestinal**

Abdominal pain, nausea, vomiting and diarrhoea (see PRECAUTIONS).

**Hypersensitivity Reactions**

Maculopapular rash and urticaria have been observed during drug therapy. Generalised mild to moderate morbilliform-like skin rashes are the most frequently reported of all adverse reactions. Rare instances of erythema multiforme, some resembling Stevens-Johnson Syndrome, have been associated with clindamycin. A few cases of anaphylactoid reactions have been reported. If a hypersensitivity reaction occurs, the drug should be discontinued. The usual agents (adrenaline, corticosteroids, colloid infusion, antihistamines) should be available for emergency treatment of serious reactions.

**Liver**

Jaundice and abnormalities in liver function tests have been observed during clindamycin therapy.

**Skin and Mucous Membranes**

Pruritis, skin rashes, urticaria, vaginitis and rare instances of exfoliative and vesiculobullous dermatitis have been reported.

Rare cases of toxic epidermal necrolysis have been reported during post-marketing surveillance.

**Haemopoietic**

Transient neutropenia (leucopenia) and eosinophilia have been reported. Rare cases of agranulocytosis and thrombocytopenia have been reported. No direct cause/effect relationship to concurrent clindamycin therapy could be made in any of the foregoing.

**Cardiovascular**

Rare instances of cardiopulmonary arrest and hypotension have been reported following too rapid intravenous administration (see DOSAGE AND ADMINISTRATION).

**Musculoskeletal**

Rare instances of polyarthritis have been reported.
Nervous System
Dysgeusia.

Local Reactions
Local irritation, pain, induration and sterile abscess have been reported after intramuscular injection and thrombophlebitis after intravenous infusion. Reactions can be minimised by giving deep intramuscular injections and avoiding prolonged use of indwelling intravenous catheters.

DOSAGE AND ADMINISTRATION
Dosage and route of administration should be determined by the severity of the infection, the condition of the patient and the susceptibility of the causative micro-organism.

Adults (IM or IV Administration)
The usual daily adult dosage of clindamycin phosphate for infections of the intra-abdominal area, female pelvis and other complicated or serious infections is 1200 - 2700 mg given in 2, 3 or 4 equal doses. Doses of up to 4800 mg daily have been used successfully. Less complicated infections due to more susceptible organisms may respond to lower doses such as 600-1200 mg/day administered in 3 or 4 equal doses.

Single IM doses of greater than 600 mg are not recommended.

Children over one month of age (IM or IV Administration)
Serious infections: 15-25 mg/kg/day in 3 or 4 equal doses
More severe infections: 25-40 mg/kg/day in 3 or 4 equal doses

As an alternative to dosing on a body weight basis, children may be dosed on the basis of square metres of body surface.

Serious infections: 350 mg/m²/day
More severe infections: 450 mg/m²/day

In severe infections it is recommended that children be given no less than 300 mg per day regardless of body weight.

Parenteral therapy may be changed to oral clindamycin (DALACIN C Capsules) when the condition warrants and at the discretion of the physician.

In cases of β-haemolytic streptococcal infections, treatment should be continued for at least 10 days.
Dilution and Infusion Rates

DALACIN C Phosphate must be diluted prior to IV administration. The concentration of clindamycin in diluent for infusion should not exceed 12 mg per mL AND INFUSED AT A RATE OF NOT MORE THAN 30 MG PER MINUTE AS INDICATED BELOW:

Table 2: Dilution and Infusion Rates in Relation to Total Infusion Dose

<table>
<thead>
<tr>

</table>

Administration of more than 1200 mg in a single 1-hour infusion is not recommended.

Directions for use

The neck of the ampoule is pre-scored at the point of constriction (no ampoule file is needed to open the ampoules). A coloured dot on the ampoule head helps to orientate the ampoule. Take the ampoule and face the coloured dot. The ampoule opens easily by placing the thumb on the coloured dot and gently pressing downwards.

Compatibility/Incompatibility

DALACIN C Phosphate has been known to be physically and chemically compatible for at least 24 hours in glucose 5% water and sodium chloride injection solutions containing the following antibiotics in usually administered concentrations: amikacin sulfate, aztreonam, cephamandole nafate, cephazolin sodium, cefotaxime sodium, ceftoxitin sodium, ceftriaxone sodium, gentamicin sulfate, netilmicin sulfate, piperacillin and tobramycin. The compatibility and duration of stability of drug mixtures will vary depending on concentration and other conditions.

No incompatibility has been demonstrated with the antibiotics cephalothin, kanamycin, gentamicin, penicillin or carbenicillin.

The following drugs are physically incompatible with DALACIN C Phosphate: ampicillin, phenytoin sodium, barbiturates, aminophylline, calcium gluconate, magnesium sulphate, ceftriaxone sodium and ciprofloxacin.

OVERDOSAGE

The minimal toxic or lethal dose is not well established. At therapeutic doses, the primary toxic effects may involve the gastrointestinal tract and may include severe diarrhoea and pseudomembranous colitis that may result in death. Rapid administration of large doses has resulted in ventricular dysrhythmias, hypotension and cardiac arrest. Dermatitis, nephrotoxicity, hepatoxicity, and various haematological abnormalities are toxic effects that occur less frequently.
No specific antidote is known. Support respiratory and cardiac function. In cases of overdose, drug levels of clindamycin are not clinically useful. However, monitoring serum concentrations in patients with markedly reduced renal and hepatic function, may be indicated during high-dose therapy. Monitor full blood count in patients with significant exposure as clindamycin may produce abnormalities of the haematopoietic system. Because clindamycin may cause hepatotoxicity, monitor liver function tests in patients with significant exposure.

Neither haemodialysis nor peritoneal dialysis appear to be effective in reducing clindamycin levels significantly.

Serious anaphylactoid reactions require immediate emergency treatment with adrenaline. Oxygen and intravenous corticosteroids should also be administered as indicated.

Contact the Poisons Information Centre for advice on the management of an overdose.

**PRESENTATION**

Each 1 mL of DALACIN C Phosphate contains clindamycin phosphate equivalent to 150 mg clindamycin base; 9.45 mg benzyl alcohol; 0.5 mg disodium edetate; and Water for Injections q.s. When necessary, pH is adjusted with sodium hydroxide and/or hydrochloric acid.

The following sizes are available:

- 2 mL ampoule (300 mg) - 10's
- 4 mL ampoule (600 mg) - 10's

Store at 2°C to 8°C (Refrigerate. Do not freeze)

**Also available for oral administration:**

Capsules 150 mg - Each capsule contains clindamycin hydrochloride hydrate equivalent to 150 mg clindamycin base.

Please consult prescribing information on oral formulations for further details.
