**PRODUCT INFORMATION**

**Name of the Medicine**

Active ingredient: Clonazepam.

Chemical name: 5-(2-chlorophenyl)-1,3-dihydro-7-nitro-2H-1,4-benzodiazepin-2-one.

Structural formula:

![Structural formula of Clonazepam](image)

Molecular formula: $C_{15}H_{10}ClN_3O_3$

Molecular weight: 315.7

CAS Registry No: 1622-61-3

**Description**

Clonazepam is a light yellow powder which is practically insoluble in water.

Paxam 0.5 tablets contain 0.5 mg of clonazepam. Each tablet also contains lactose, cellulose - microcrystalline, starch - maize and magnesium stearate and sunset yellow FCF CI15985.

Paxam 2 tablets contain 2 mg of clonazepam. Each tablet also contains lactose, cellulose - microcrystalline, starch - maize and magnesium stearate.

**Pharmacology**

**Actions**

Clonazepam is an anticonvulsant, which exhibits several pharmacological properties characteristic of the benzodiazepine class of medicines.

The exact site and mode of the anticonvulsant action of clonazepam is unknown.

Benzodiazepines enhance the polysynaptic inhibitory processes at all levels of the central nervous system. Clonazepam is more effective in blocking spread of electrical activity in the lesion itself.
Pharmacokinetics

Absorption and Bioavailability

Clonazepam is rapidly and almost completely (82 – 98%) absorbed after oral administration, with peak serum levels being reached between 2 to 3 hours. The absorption half-life is 24 min. Accumulation occurs with continuous therapy, and although values differ in different reports, the therapeutic serum level appears to be between 10 and 80 nanogram/mL. In one study with increase in dosage to 5 mg/day, the average level of clonazepam after 15 days was 54 nanogram/mL. A steady state is usually reached within 2 to 3 weeks.

Plasma concentrations of clonazepam at steady states for once daily dosage regimes are 3-fold higher than those after single oral doses. Following multiple oral doses of 2 mg three times daily, steady-state pre-dose plasma concentrations of clonazepam ranged from 30 - 80 nanogram/mL. The plasma concentration-dose relationship of clonazepam is linear.

The absolute bioavailability is 90%.

Distribution

Clonazepam enters the cerebral tissues rapidly.

The distribution half-life is approximately between ½ hour and 1 hour. The apparent volume of distribution (3 L/kg) suggests concentration in some tissues.

The plasma protein binding of clonazepam ranges from 82 - 86%.

Metabolism

Clonazepam is metabolised in the liver. Metabolic pathways include hydroxylation, reduction of the nitro groups to an amine and addition of acetate to the amino grouping. Clonazepam is extensively metabolised by reduction to 7-amino-clonazepam and by N-acetylation to 7-acetamido-clonazepam. Hydroxylation at the C-3 position also occurs. Hepatic cytochrome P-450 3A4 is implicated in the nitroreduction of clonazepam to pharmacologically inactive metabolites.

Elimination

The mean elimination half-life is 39.0 ± 8.3 hours. The mean clearance ± SD is 55.1 ± 8.2 mL/min following a single dose of 2 mg clonazepam given intravenously.

50 – 70% of the dose is excreted in the urine and 10 - 30% in the faeces as metabolites. The urinary excretion of unchanged clonazepam is usually less than 2% of the administered dose. The metabolites are present in urine both as free and conjugated (glucuronide and sulphate) compounds.

Clinical significance of pharmacokinetics

Accumulation occurs with chronic dosing. However, there is a wide variation in therapeutic plasma levels and a correlation between adverse effects with plasma levels or the rate of increase in plasma concentration of clonazepam and its metabolites has not been established. Consequently, monitoring of plasma levels, as is often done with some anticonvulsants, would be valuable.

It should be emphasised that the patient should be monitored carefully in the initial stages for clinical response and occurrence of side effects because of the effect of clonazepam on plasma levels of other anticonvulsants administered concomitantly (and vice versa).

Pharmacokinetics in Special Populations

Renal Failure: Renal disease does not affect the pharmacokinetics of clonazepam. However, while based on pharmacokinetic considerations, no dosage adjustment may be required, the pharmacodynamics of probable
accumulated clonazepam metabolites may necessitate dosage review in these patients.

**Hepatic Failure:** The influence of hepatic disease on clonazepam pharmacokinetics has not been investigated. However, due to the sole hepatic metabolism of clonazepam, the pharmacokinetics of clonazepam are expected to be affected on theoretical grounds.

**Elderly:** The pharmacokinetics of clonazepam in the elderly has not been established.

**Neonates:** Although the elimination half-life (41.9 ± 29.8 h) and clearance values in neonates pre-treated with phenobarbital are the same order of magnitude as those reported in non-pretreated adults, post-natal age does however affect the clearance of clonazepam under normal conditions.

### Indications

Most types of epilepsy in children, especially absences (petit mal), myoclonic seizures and tonic-clonic fits, whether due to primary generalised epilepsy, or to secondary generalisation of partial epilepsy.

In adults, all varieties of generalised epilepsy (including myoclonic, akinetic, tonic and tonic-clonic seizures), and in partial epilepsy (including psychomotor seizures).

### Contraindications

Clonazepam is contraindicated in patients with

- known hypersensitivity to benzodiazepines
- known hypersensitivity to any of the excipients in Paxam
- chronic obstructive airways disease with incipient respiratory failure
- dependence on drugs of abuse and CNS depressants including alcohol
- severe hepatic insufficiency

### Precautions

Only a small minority of patients with the common seizure types achieve a lasting remission with clonazepam. Tolerance to the anticonvulsant effect may occur after four weeks to six months of continuous treatment in the majority of patients, leading to increased seizure frequency. Increasing the dose in this situation is rarely worthwhile. If seizures are no longer being adequately controlled, the medicine should be discontinued and alternative treatment implemented.

**Concomitant use of alcohol and CNS depressants**

The concomitant use of clonazepam with alcohol and/or CNS depressants has the potential to increase the clinical effects of clonazepam; possible effects include severe sedation, clinically relevant respiratory and/or cardiovascular depression.

Since alcohol can provoke epileptic seizures irrespective of therapy and may potentiate the CNS depressant effects of clonazepam, it is imperative that patients abstain from drinking alcohol while under treatment with clonazepam. Patients should be advised that their tolerance for alcohol and other CNS depressants will be
diminished and that these medications should either be eliminated or given in reduced dosage in the presence of Paxam.

Paxam should be used with particular care in spinal or cerebellar ataxia; in the event of acute intoxication with alcohol, other antiepileptic medicines, hypnotics, analgesics, neuroleptic agents, antidepressants or lithium; or if the patient suffers from sleep apnoea.

As up to 70% of clonazepam metabolites are excreted via the kidneys, the pharmacodynamics of clonazepam and its metabolites might be altered.

**Lactose intolerance**
Since Paxam contains lactose, patients with rare hereditary problems of galactose intolerance (the Lapp lactase deficiency or glucose-galactose malabsorption) should not take this medicine.

**Hypotension**
Although hypotension has occurred only rarely, Paxam should be administered with caution to patients in whom a drop in blood pressure might lead to cardiac or cerebral complications. This is particularly important in elderly patients.

**Amnesia**
Transient amnesia or memory impairment has been reported in association with the use of benzodiazepines.

**Myasthenia gravis**
Clonazepam could increase the muscle weakness in myasthenia gravis and should be used with caution in this condition.

**Acute narrow-angle glaucoma**
Caution should be used in the treatment of patients with acute narrow angle glaucoma (because of atropine-like side effects).

**Impaired renal/hepatic function and blood dyscrasias**
Patients with impaired renal or hepatic function should use benzodiazepine medication with caution and dosage reduction may be advisable. In rare instances, patients on benzodiazepines have developed blood dyscrasias, and some have had elevations of liver enzymes. Periodic blood counts and liver function tests are recommended in patients in whom benzodiazepine therapy for periods longer than four weeks is deemed necessary.

**Paradoxical reactions**
Paradoxical reactions such as agitation, nervousness, hostility, anxiety, sleep disturbances, nightmares, vivid dreams, acute rage, stimulation or excitement may occur. Paxam should be discontinued if such reactions occur.

**Impaired respiratory function**
Caution in the use of Paxam is recommended in patients with respiratory depression. In patients with chronic obstructive pulmonary disease, benzodiazepines can cause increased arterial carbon dioxide tension and decreased oxygen tension.

**Depression, psychosis and schizophrenia**
Paxam is not recommended as primary therapy in patients with depression and/or psychosis. In such conditions, psychiatric assessment and supervision are necessary if benzodiazepines are indicated. Benzodiazepines may increase depression in some patients, and may contribute to deterioration in severely disturbed schizophrenic patients with confusion and withdrawal. Suicidal tendencies may be present or uncovered and protective measures may be required.
Epilepsy
When clonazepam is administered to persons with convulsive disorders, an increase in the frequency and/or severity of grand mal seizures may occur, necessitating increased anticonvulsant medication. Abrupt withdrawal of benzodiazepines in persons with convulsive disorders may be associated with a temporary increase in the frequency and/or severity of seizures.

Abuse
Caution must be exercised in administering Paxam to individuals known to be addiction prone or those whose history suggests they may increase the dosage on their own initiative. It is desirable to limit repeat prescription without adequate medical supervision.

Dependence
The use of benzodiazepines may lead to dependence, as defined by the presence of a withdrawal syndrome on discontinuation of the medicine. Tolerance, as defined by a need to increase the dose in order to achieve the same therapeutic effect, seldom occurs in patients receiving recommended doses under medical supervision. Tolerance to sedation may occur with benzodiazepines, especially in those with drug seeking behaviour.

Withdrawal symptoms similar in character to those noted with barbiturates and alcohol have occurred following abrupt discontinuation of benzodiazepines. These symptoms range from insomnia, anxiety, dysphoria, palpitations, panic attacks, vertigo, myoclonus, akinesia, hypersensitivity (to light, sound or touch), abnormal body sensations (e.g. feeling of motion, metallic taste), depersonalisation, derealisation, delusional beliefs, hyperreflexia, loss of short-term memory, to a major syndrome which may include convulsions, tremor, abdominal and muscle cramps, confusional state, delirium, hallucinations, hyperthermia, psychosis, vomiting and sweating. Such manifestations of withdrawal, especially the more serious ones, are more common in those patients who have received excessive doses over a prolonged period of time. However, withdrawal symptoms have also been reported following abrupt discontinuation of benzodiazepines taken continuously at therapeutic levels. Accordingly, Paxam should be terminated by tapering the dose to minimise the occurrence of withdrawal symptoms. Patients should be advised to consult with their physician before either increasing the dose or abruptly discontinuing this medication.

Following the prolonged use of clonazepam at therapeutic doses, withdrawal from the medication should be gradual. An individualised withdrawal timetable needs to be planned for each patient in whom dependence is known or suspected. Periods from 4 weeks to 4 months have been suggested. As with other benzodiazepines, when treatment is suddenly withdrawn, a temporary increase in sleep disturbance can occur after the use of clonazepam.

Rebound phenomena have been described in the context of benzodiazepine use. Rebound insomnia and anxiety mean an increase in the severity of these symptoms beyond pretreatment levels following cessation of benzodiazepines. Rebound phenomena, in general, possibly reflect the re-emergence of pre-existing symptoms combined with the withdrawal symptoms described earlier. Some patients prescribed benzodiazepines with very short half lives (in the order of 2 - 4 hours) may experience relatively mild rebound symptoms in between their regular doses. Withdrawal/rebound symptoms may follow high doses for relatively short periods.

Porphyria
Clonazepam should be used with care in patients with porphyria because it may have a porphyrogenic effect.

Effects on Fertility
Dietary administration of clonazepam to male and female rats was associated with a reduced pregnancy rate.
and impaired pup survival at doses of 60 mg/m²/day or greater (4-fold the maximal recommended human dose [MRHD]); the no-effect dose was 6 mg/m²/day (less than clinical exposure).

**Use in Pregnancy (Category B3)**
The risk of a mother with epilepsy and taking anticonvulsants giving birth to a baby with an abnormality is about three times that of the general population. Some of this risk is due to the anticonvulsant medicines taken. Mothers taking more than one anticonvulsant medicine have a higher risk of having a baby with a malformation than mothers taking one medicine.

Overall the risk of having an abnormal child is far outweighed by the dangers to the mother and foetus of uncontrolled convulsions. It is therefore recommended that:

- women on anticonvulsant medicines receive pre-pregnancy counselling with regard to the risk of foetal abnormalities;
- anticonvulsants should be continued during pregnancy and monotherapy should be used if possible at the lowest effective dose;
- folic acid supplement (5 mg daily) should be commenced four weeks prior to and continue for twelve weeks after conception;
- specialist prenatal diagnosis including detailed mid-trimester ultrasound should be offered.

Clonazepam is a benzodiazepine. These medicines cross the placenta and appear in the foetus and may after continuous administration during a large part of pregnancy, give rise to hypotonia, reduced respiratory function and hypothermia in the newborn child. Withdrawal symptoms in newborn infants have occasionally been reported with this class of medicines.

Oral administration of clonazepam during the period of organogenesis has elicited a low, non-dose-related incidence of a similar pattern of malformations in rabbits (cleft palate, open eyelids, fused sternebrae, limb defects) and mice (exencephaly, central nervous system defects) at doses less than MRHD. These effects were not observed in rats at oral doses more than 20-fold MRHD. The clinical significance of these findings is unknown.

**Use in Lactation**
Paxam must not be given to breastfeeding women. Clonazepam is excreted in human breast milk, and may cause drowsiness and feeding difficulties in the infant.

If there is a compelling reason for use of clonazepam, breast feeding should be discontinued.

**Paediatric and Neonatal use**
Salivary and bronchial hypersecretion can occur in infants and small children, and supervision is required to ensure that airways remain free, especially on commencing therapy or in the event of respiratory infection.

**Elderly or debilitated patients**
An increased risk or falls and fractures has been recorded in elderly benzodiazepine users.

Elderly or debilitated patients may be particularly susceptible to the sedative effects of benzodiazepines and associated giddiness, ataxia and confusion, which may increase the risk of a fall.

Elderly patients, patients with pre-existing disease of the respiratory system (e.g. chronic obstructive lung disease), liver disease or kidney disease, or those who are receiving treatment with other centrally acting medications or anticonvulsant agents, require very cautious dosage adjustment.
Carcinogenicity
No 2-year carcinogenicity studies have been conducted with clonazepam. An 18-month chronic study in rats showed no treatment-related histopathological changes at dietary doses up to 1800 mg/m²/day (greater than 100-fold MRHD).

Genotoxicity
Clonazepam and five of its metabolites were negative in bacterial gene mutation assays. Chromosomal damage assays have not been conducted with clonazepam.

Interactions with Other Medicines
Clonazepam can be administered concurrently with one or more other antiepileptic medicines, in which case the dosage of each medicine must be adjusted to achieve the optimum effect. Interactions have been reported between some benzodiazepines and other anticonvulsants, with changes in the serum concentration of the benzodiazepine or anticonvulsant. It is recommended that patients be observed for altered responses when benzodiazepines and anticonvulsants are prescribed together, and that serum level monitoring of the anticonvulsant be performed more frequently.

Pharmacokinetic Interactions
The anti-epileptic medicines phenytoin, phenobarbitone, carbamazepine and valproate may increase the clearance of clonazepam, thereby decreasing the plasma concentrations of the latter during combined treatment. Clonazepam itself does not appear to induce the enzymes responsible for its own metabolism.

The selective serotonin reuptake inhibitors sertraline and fluoxetine do not significantly affect the pharmacokinetics of clonazepam when administered concomitantly.

Phenytoin - the effect of clonazepam on phenytoin plasma levels is not clear as the latter may increase or decrease according to study reports.

Carbamazepine - levels may be lowered by clonazepam.

Pharmacodynamic Interactions
Benzodiazepines, including clonazepam, produce additive CNS depressant effects when co-administered with other medications which themselves produce CNS depression, e.g. other anticonvulsant (anti-epileptic) agents, lithium, barbiturates, sedatives, tricyclic antidepressants, non-selective MAO inhibitors, phenothiazines and other antipsychotics, skeletal muscle relaxants, antihistamines, narcotic analgesics and anaesthetics. This is especially true in the presence of alcohol (see earlier section of Precautions).

Clonazepam undergoes oxidative metabolism and, consequently, may interact with disulfiram or cimetidine resulting in increased plasma levels of clonazepam. Patients should be observed closely for evidence of enhanced benzodiazepine response during concomitant treatment with either disulfiram or cimetidine; some patients may require a reduction in benzodiazepine dosage.

The anticholinergic effects of atropine and similar medicines, antihistamines and antidepressants may be potentiated.

Minor EEG changes, usually low voltage fast activity, of no known clinical significance, has been reported with benzodiazepine administration.

Some specific interactions noted with clonazepam are:

Alcohol - epileptic patients should not under any circumstances consume alcohol while being treated with
clonazepam, since alcohol may alter the effect of the medicine, reduce the efficacy of treatment or produce unexpected side effects (see earlier section of Precautions).

Valproate sodium - reports of sodium valproate causing petit mal status epilepticus with clonazepam exist.

**Effects on ability to drive or operate machinery**

As with all patients taking CNS depressant medications, patients receiving Paxam should be warned not to operate dangerous machinery or motor vehicles until it is known that they do not become drowsy or dizzy from clonazepam therapy. Abilities may be impaired on the day following use.

**Adverse Effects**

Adverse effects to clonazepam occur in about 50% of patients (depending on dose); they are usually attributable to its sedative and muscle relaxant effects and are generally transitory. However, they can continue in up to 10% of patients and may result in withdrawal of the medicine. Adverse effects can, to a certain extent, be avoided by a low initial dose and gradual increase in dosage.

**More common adverse effects.** Drowsiness or somnolence (50%), ataxia (30%), behaviour problems (25%), hypersalivation (10%), fatigue (8%), muscle weakness (5%), vertigo (5%) and lightheadedness, tiredness, sleepiness, lassitude and dizziness.

These effects are generally temporary and usually disappear during treatment either spontaneously or by dose reduction.

**Less common adverse effects.** Agitation (1.5%), excitability (0.7%), irritability (1.5%), aggressive behaviour (1.4%), disturbances of concentration, depression (1%), confusion (1.9%), bronchial hypersecretion (1.4%), slowed reactions and antero-grade amnesia, restlessness and disorientation have been observed.

With certain forms of epilepsy, an increase in the frequency of seizures during long-term treatment is possible.

Even if taken as directed, clonazepam can slow reactions to such an extent that the ability to drive a vehicle or operate machinery is seriously impaired. The effect is increased if the patient has also taken alcohol (see Precautions, Effects on ability to drive or operate machinery).

Dosage and Administration

Dosage of clonazepam is essentially individual and depends in the first instance on the age of the patient. It will be determined in each patient according to clinical response and tolerance. In order to minimise initial adverse effects, it is essential to commence with low doses and increase the daily dose progressively until a maintenance dose suited to the individual patient has been reached. Some degree of tolerance may be observed to both the adverse and therapeutic effects. If epilepsy is not adequately controlled at the maximum recommended dosage level, alternative or combination therapy should be considered (see Precautions).

**Dosage for initiation of therapy:**

**Children:**
- 2 to 5 years: 0.5 mg/day (half a 0.5 mg tablet morning and evening);
- 6 to 12 years: 0.75 mg/day (half a 0.5 mg tablet in the morning, one 0.5 mg tablet in the evening).

**Adults:**
- 1 mg/day (one 0.5 mg tablet morning and evening).
Average dosage range for maintenance therapy:

<table>
<thead>
<tr>

<tr>
<td>School children (6-12 years)</td>
<td>3 – 6</td>
<td>6 – 12</td>
<td>1 1/2 – 3</td>
</tr>
<tr>
<td>Adults*</td>
<td>4 – 8</td>
<td>8 – 16</td>
<td>2 – 4</td>
</tr>
</tbody>
</table>

* Maximum therapeutic dose is 20 mg/day

The daily quota should, if possible, be divided into three or four doses spread over the day.

The maintenance dose should be reached after two to four weeks of treatment. To obtain optimum adjustment of the dose in children, the 0.5 mg tablets should be used.

**Use in the elderly:** Elderly patients are usually more sensitive to the effects of benzodiazepines. Particular care should be taken during up-titration in elderly patients. The maintenance dose will usually be in the lower range of adult dosage (see **Precautions**).

**Impaired hepatic function.** The safety and efficacy of clonazepam in patients with hepatic impairment has not been studied. No data are available on the pharmacokinetics of clonazepam in hepatic disease. Reduced dosage may be necessary as clonazepam is mainly metabolised in the liver.

**Impaired renal function.** The safety and efficacy of clonazepam in patients with renal impairment has not been studied. However, based on pharmacokinetic considerations no dose adjustment is required in these patients (see **Pharmacology – Pharmacokinetics in Special Populations**).

**Overdosage**

**Symptoms**

Overdosage of benzodiazepines is usually manifested by degrees of central nervous system depression ranging from drowsiness to coma. In mild cases, symptoms include drowsiness, mental confusion and lethargy. In more serious cases, symptoms may include ataxia, dysarthria, nystagmus, hypotonia, hypotension, respiratory depression, coma, and very rarely death. Coma may be more protracted and cyclical, particularly in elderly patients. Benzodiazepine respiratory depressant effects are more serious in patients with respiratory disease.

Benzodiazepines increase the effects of other central nervous system depressants, including alcohol. When combined with other CNS depressants, the effects of overdosage are likely to be severe and may prove fatal.

**Treatment**

Treatment of overdose is symptomatic; institute supportive measures as indicated by the patient's clinical state. If the overdosage is known to be small, observation of the patient and monitoring of their vital signs only may be appropriate. In adults or children who have taken an overdose of benzodiazepines within one to two hours, consider activated charcoal with airway protection if indicated.

If CNS depression is severe consider the use of flumazenil (Anexate®), a benzodiazepine antagonist. This should only be administered under closely monitored conditions. It has a short half-life (about an hour), therefore patients administered flumazenil will require monitoring after its effects have worn off. Flumazenil may precipitate
seizures and is to be used with extreme caution in the presence of medicines that reduce seizure threshold (e.g. tricyclic antidepressants) and epileptic patients who have been treated with benzodiazepines. Refer to the prescribing information for flumazenil (Anexate®), for further information on the correct use of this medicine.

Haemoperfusion and haemodialysis are not useful in benzodiazepine intoxication.

Contact the Poisons Information Centre on 131126 (Australia) for advice on the management of overdosage.

**Presentation and Storage Conditions**

**Paxam 0.5** Clonazepam 0.5 mg tablet: peach coloured, marked CN on one side, cross scored on the reverse; 100's.

**Paxam 2** Clonazepam 2 mg tablet: white, marked CN on one side, cross scored on the reverse; 100's.

Store below 25°C.
